Abstract

It is determined that arboreal and limestone-dweller species of Antillean *Leptocephalus* conform a monophyletic group, named *Macromischa*, defined as the least inclusive clade that includes *L. sallei* and *L. myersi*, but not *L. isabellae*. The following morphological species groups are defined and diagnosed: Arboreal species: *sallei*, *squamifer* (subgroups *squamifer* and *splendens*), *gibbifer*, *purpuratus*, *punicans*. Limestone-dweller species: *versicolor* (subgroups *iris*, *porphyrytis*, *versicolor*). The Puerto Rican arboreal species, *L. isabellae*, is the *Macromischa*'s sister taxon. This more inclusive clade is named *Macromischamorpha*.

Resumen

Se determina que las especies arborícolas y carsífilicas de *Leptocephalus* de las Antillas conforman un grupo monofilético, nombrado *Macromischa*, definido como el clado menos inclusivo que incluye *L. sallei* y *L. myersi*, pero no *L. isabellae*. Se definen y diagnostican los siguientes grupos morfológicos de especies. Arborícolas: *sallei*, *squamifer* (subgrupos *squamifer*, *splendens*), *gibbifer*, *purpuratus*, *punicans*. Carsífilicos: *versicolor* (subgrupos *iris*, *porphyrytis*, *versicolor*). La especie arborícola de Puerto Rico, *L. isabellae*, es el taxón hermano de *Macromischa*. Este clado más inclusivo es nombrado *Macromischamorpha*.

Key words: Ants, *Leptocephalus*, *Macromischa*, phylogenetic analysis.

Palabras claves: Hormigas, *Leptocephalus*, *Macromischa*, análisis filogenético.

INTRODUCTION

All of the Antillean *Leptocephalus*, along with a group of species from Central America and the South of the United States, were placed in the genus ad hoc, *Macromischa* Roger, 1863, until BARONI-URBANI'S (1978) revision. He defined 12 species groups within the former *Macromischa* and treated it as a subgenus, with ambiguous limits and possibly polyphyletic, of *Leptocephalus*. SNELLING (1986) synonymized formally the taxon, and this is the most accepted general consideration so far (BOLTON, 1994, 1995).

Within the Antillean *Leptocephalus*, which conforms the richest group, both in species number and endemism, of all of the Antillean ants, it can be distinguished three general ecological species groups: **a)** terricolous: built their nests on soil. **b)** arboreal: built their nests in epiphytes, fallen trunks, holes in the trees or making a cartoon nest in the bran-

ches. c) limestone-dweller: built their nests in crevices of limestone, making a cartoon tubular entrance. This is an unique trait among ants.

The species in the arboreal and limestone- dweller groups exhibit a heterogeneous arrangement of traits like bizarre morphology and sculpturation and unusual color patterns. This, together with the singular nesting behavior of the limestone-dweller species, makes all of them one of the most remarkable group of ants in the whole world.

The purpose of the present paper is to define and to determine, through a phylogenetic analysis, a possible natural taxon as well as morphological species groups within the Antillean *Leptothorax*

MATERIAL AND METHODS

Taxa. There were analyzed the 47 species of Antillean *Leptothorax*. It was followed the taxonomic arrangement of BARONI-URBANI (1978), with later modifications and/or additions of SNELLING (1986) and FONTENLA (1997, 1998). It was not possible to examine specimens of *L. ciferrii*, *L. pulchellus*, *L. creolus* and *L. praecreolus*†. Characters selection and measurements of these species were taken from BARONI-URBANI (1978) for the extant taxa and from ANDRADE (1992) for the fossil species. The rest of the species were examined from the following collections: Cuba: Instituto de Ecología y Sistemática, Museo Nacional de Historia Natural. USA: American Museum of Natural History, Museum of Comparative Zoology at University of Harvard, National Museum of Natural History.

Characters. There were selected 52 morphological and one ecological-behavioural characters from workers (Appendix 1). Exclusive characters for particular species were not considered in the phylogenetic analysis (Appendix 3). Multistated characters were treated as unordered.

Polarization and outgroups. Polarization was made through an unconstrained and simultaneous analysis, as part of the cladistic performance. It was selected as prime outgroup *Cardiocondyla emeryi*. This genus is very close to *Leptothorax* (BOLTON, 1982; FRANCOEUR AND LOISELLE, 1988). *C. emeryi* is a widespread and very well known species with a conservative morphology. The second outgroup was *Leptothorax acervorum*, the type species of the genus, *sensu* BOLTON (1982, 1995).

Phylogenetic analysis. It was employed PAUP 3.1.1 program (SWOFFORD, 1993). Tree search was made by branch swapping together with tree bisection and reconnection. The choice of the final hypothesis of relationships was made after the application of successive weighting with the rescaled consistency index. Assumptions and comments of this method of reducing solutions in CARPENTER (1988, 1994) and EGGLETON AND VAN-WRIGTH (1994). Tree manipulation and edition with MacClade version 3.05 (MADDISON AND MADDISON, 1995).

Pylogenetic definitions. I follow here the approach to phylogenetic definitions sustained by SHANDER AND THOLLESSON (1995), MICHAEL (1995, 1998) and DOMINGUEZ AND WHEELER (1997), instead of the traditional approach (DE QUEIROZ, 1996, 1997 and references therein). They do not consider ancestry-descendant relationships as part of the phylogenetic definitions. For population level definition I follow DE QUEIROZ (1992).

RESULTS AND DISCUSSION

Cladistic analysis yielded 952 equally parsimonious trees (EPT) with Length (L)= 239 steps, Consistency Index (CI)= 0.28 and Retention Index (RI)= 0.78. After successive weighting, solutions were reduced to 2 EPT with CI= 0.52 and RI= 0.91. Strict consensus tree (Fig. 1) shows a clade (*) whose species share the following characters states: 24(0), 33 (1,2), 34(1), 35(1), 3(1), 53 (1,2). This clade includes all of the original species of *Macromischa*. *L. isabellae* is its sister group, sharing characters states 24(0), 34(1), 53(1). *L. praecreolus*[†] is the sister taxon of this more inclusive clade, sharing character state 34(1), and probable 53(1), according to the most probable parsimonious reconstruction. The *terricolous* species conform the BARONI-URBANIS's (1978) *allardycei*, *creolus*, *pastinifer* and *pulchellus* morpho-logical groups. The *pulchellus* group appears to be polyphyletic (Composition of Baroni-Urbani's 1978 groups in Appendix 2).

In an attempt to refine the phylogenetic relationships of the arboreal + limestone dweller clade, it was removed the *terricolous* group and added to the root its sister species. The characters states were properly recodified when needed. The new performance produced 166 EPT with L= 183, CI= 0.35 and RI=0.74 . Successive weighting resulted in one tree (Fig. 2); with CI=0.61 and RI= 0. 88. Manipulation with MacClade did not reveal any shorter alternative tree topology.

Bootstrap majority-rule consensus tree (Fig. 3) shows support above 50% for all the branches. Generation of 10 000 random trees from the data matrix produced a tree frequency between 363 and 480 steps, with a mean value of 433.1 steps. This indicates that the most parsimonious reconstruction (183 steps) is very far from a chance solution and so the data contain a strong phylogenetic signal.

The arboreal + limestone dweller clade of Antillean *Leptothorax* can be named *Macromischa*. The meaning of this name is to point to a natural (monophyletic) group of species within the genus *Leptothorax*, which has evolved in a very specific biogeographical context: Cuba and the Hispaniola, producing two ecological and morphological well defined species groups. *Macromischa* can be defined (stem-based) as: the least inclusive clade that includes *L. sallei* and *L. myersi*, but not *L. isabellae*. The more inclusive clade composed by *Macromischa* and its sister taxon, *L. isabellae*, can be named as *Macromischamorpha* and defined (node-based) as: the least inclusive clade that includes *L. isabellae* and *Macromischa*. Morphological species groups of *Macromischa* (named according to nomenclatural priority).

1. *Sallei*. Definition: The least inclusive clade of *Macromischa* that includes *L. sallei* and *L. laetus*. Composition: *L. bruneri*, *L. dissimilis*, *L. laetus*, *L. hispaniolae*, *L. sallei*. Diagnosis: Arboreal species of medium size, slender constitution and straight profile. Club differentiated, scapes thin and short. Propodeal spines long. Petiole long, node square and high. Postpetiole broader than long. Femora medium. Femorae and tibiae inflated. Tegumentary sculpturation mainly longitudinal.

BARONI-URBANI (1978) included within his *sallei* group six species from Mexico and Central America. Cladistic analysis produced 40 EPT with L= 255, CI=0.26, and RI= 0.69. Successive weighting gave a single tree (CI= 0.40, RI= 0.80), which shows these spe-

cies as not belonging to *Macromischa* (Fig. 4).

2. *Squamifer*. Definition : The least inclusive clade of *Macromischa* that includes *L. squamifer* and *L. splendens*. Composition: *Squamifer* subgroup: *L. platycnemis*, *L. barbouri*, *L. creigthoni*, *L. squamifer*. *Splendens* subgroup: *L. violaceus*, *L. splendens*, *L. darlingtoni*, *L. abeli*. Diagnosis: Arboreal species of big and medium size. Curvilinear or straight profile. Scapes thick and short. Propodeal spines present. Node scale shaped, high and broader than long. Postpetiole broader than long. Femora medium. Femorae and tibiae inflated. Tegument with iridescent or metallic reflections. *Squamifer* subgroup. Spines long. Petiole long or very long; node broader than the postpetiole. *Splendens* subgroup. Pronotum and mesonotum broad. Propodeal spines and petiole short. Femora with small tubercles.

3. *Gibbifer*. Definition: Types specimens of *L. gibbifer* Baroni-Urbani, 1978 and all other organisms relationed to those organisms through interbreeding to form an inclusive population level lineage. Composition: *L. gibbifer*. Diagnosis: Arboreal species of small size. Massive constitution and curvilinear profile. Club differentiated; scapes thick and short. Propodeal spines short. Petiole short; node rounded and high, with no anterior face and broader than long. Postpetiole broader than long. Femora medium. Femora and tibiae inflated. Tegument with iridescence. Reticulated sculpturation.

4. *Purpuratus*. Definition: The least inclusive clade that includes *L. alayoi* and *L. purpuratus*. Composition: *L. alayoi* and *L. purpuratus*. Diagnosis: Arboreal species of slender constitution. Club differentiated; scapes thick and short. Propodeal spines present. Petiole very long. Node rounded and very low, with no anterior face, longer than broad. Postpetiole longer than broad. Femora and tibiae inflated. Head with iridescent tegument.

5. *Punicans*. Definition: Types specimens of *L. punicans* Roger, 1863 and all the other organisms relationed to those organisms through interbreeding to form an inclusive population level lineage. Composition: *L. punicans*. Diagnosis: Arboreal species of big size and sinuous profile. Club differentiated; scapes thick and short. Propodeal spines absent. Petiole long, node rounded, low with no anterior face, longer than broad. Tibiae no inflated. Postpetiole longer than broad. Mesosoma punctuated and longitudinal striated.

6. *Versicolor*. Definition: The least inclusive clade of *Macromischa* that includes *L. iris*, *L. porphyrytis* and *L. versicolor*. Composition: *Iris* subgroup: *L. gundlachi*, *L. wheeleri*, *L. barroi*, *L. iris*, *L. senectutis*. *Porphyrytis* subgroup: *L. mortoni*, *L. nipensis*, *L. villarensis*, *L. banao*, *L. myersi*. *Versicolor* subgroup: *L. versicolor*, *L. bermudezi*, *L. poeyi*. Diagnosis: Slender constitution, club poorly differentiated, scapes thin and long or very long. Petiole long or very long; node rounded, longer than broad. Postpetiole longer than broad (except in *L. myersi*). Tibiae no inflated. Iris subgroup: scapes surpassing CL in less than 140%. Propodeal spines absent. Petiole long. Femora medium. Tegument with iridescent and/or metallic reflections. *Porphyrytis* subgroup: scapes surpassing CL in less than 140%. Propodeal spines long or very long. Petiole long or very long. Femora long. *Versicolor* subgroup: Scapes surpassing CL in more than 140%. Pronotum oblong. Propodeal spines absent. Petiole long. Femora long.

Appendix 1. Characters and codification.

Apéndice 1. Caracteres y codificación.

1. CW/CL £ 75% (0), CW/CL ≥ 75% (1). CW: Cephalic width. CL: Cephalic length.
2. Antennal club: little differentiated (0), well differentiated (1).
3. Number of segments in the club: 3 (0), 4 (1).
4. Shape of funiculum segments: rounded (0), rectangular (1).
5. Scape: thick (0), thin (1).
6. Scape: short (0), long (1), very long (2).
Short: do not surpass CL, long: surpassing CL less than 140%, very long: surpassing more than 140%.
7. Size: small (0), medium (1), big (2).
Small \leq 35 mm, medium $>$ 3.5 mm $<$ 5.0 mm, big \geq 5.0 mm.
8. Profile : straigth (0), curvilinear (1), convex (2), sinuous (3).
9. Pronotum shape in profile: no oblong (0), oblong (1).
10. General body structure: massive (0), slender (1).
11. Pronotum width /Mesosoma length : broad \geq 50% (0), narrow £ 50% (1).
12. Mesonotum width/Pronotum width: Broad \geq 85% (0), narrow £ 85% (1).
13. Metanotum width/ mesonotum width: $>$ 100 (0), $<$ 100 (1).
14. Metanotum width/pronotum width \geq 75% (0), £ 75% (1).
15. Petiole length, measured as petiole lenght /mesosoma length ratio: short (<45%) (0), long (>45% $<$ 50%) (1), very long (> 50%) (2).
16. Petiole node heighth, measured as petiole node heighth (PH)/petiole length (PL) ratio: low (< 40%) (0), high (\geq 40%, \leq 50%) (1), (>50%) (2).
17. Petiole node width (PW)/petiole lenght (PL): narrow (\leq 45%) (0), broad (> 45%) (1).
18. Petiole node: taller than broad (0), broader than tall (1).
19. Petiole node: broader than long (0), longer than broad (1).
20. Petiole node: less broad than postpetiole (0), broader than postpetiole (1).
21. Petiole node without an anterior defined face (0), with an anterior defined face (1).
22. Petiole node shape in profile: square or subsquare (0), rounded (1), scale (2), anterior face concave (3).
23. Postpetiole: narrow (0), broad (1), very broad (2). Narrow: longer than broad; broad: postpetiole width (PPW)/ postpetiole length (PPL) $<$ 150%; very broad: PPW/PPL $>$ 150%.
24. First segment of gaster: narrower than pronotum width (0), broader than pronotum width (1).
25. Subpetiolar process: absent (0), present (1).
26. Petiole peduncle: with no hair or very scarce hair (0), hair abundant (1).
27. Propodeal spines: absent (0), short (1), long (2). Length measured as spine length (SL) /mesosoma length (ML) ratio: short: SL/ML £ 30%, long. SL/ML > 30%.
28. Maximal /minimal posterior femur width ratio: little contrasting $>$ 30% (0), contrasting \leq 30%.
29. Femora thickness: little marked (0), well marked (1).
30. Distribution of femora thickness: homogeneous throughout (0), medial (1), distal (2).
31. Femorae tubercles: absent (0), present (1).

32. Tibiae: no inflated (0), inflated (1).
 33. Posterior femorae: short (0), medium (1), long (2). Short: length \leq 70% mesosoma length (ML), medium 70% $<$ ML \leq 100%, long: > 100%ML.
 34. Promesotoraxic suture: no conspicuous or absent (0), conspicuous (1).
 35. Dominant pilosity: hairs short and blunt (0), hairs long and acuminate (1).
 36. General pilosity distribution: scarce (0), abundant (1).
 37. Scape: With no erect hairs (0), with erect hairs (1).
 38. Head: striae absent or feeble and sparsely distributed (0), striae strong and dense (1).
 39. Head: punctures absent or feeble and sparse (0), punctures marked and dense (1).
 40. Mesosoma: striae absent or feeble and sparsely distributed (0), striae strong and dense (1).
 41. Mesosoma: punctures absent or feeble and sparsely distributed (0), striae strong and dense (1).
 42. Pronotum: sculptured like the rest of mesosoma (0), sculpture absent or very feeble (1).
 43. Petiole: not striated (0), striated (1).
 44. Petiole: not punctuated (0), punctuated (1).
 45. Postpetiole: not striated (0), striated (1).
 46. Postpetiole: not punctuated (0), punctuated (1).
 47. Legs: with no microsculpturations (0), with sculpturations (1).
 48. Tegumentary iridescent: absent (0), present (1).
 49. Tegument with metallic reflections: absent (0), present (1).
 50. Tegument: no polychrome (0), polychrome (1).
 51. Gaster: with no microsculpturations (0), with microsculpturations (1).
 52. Gaster: shining or slightly shining (0), opaque (1).
 53. Nesting behaviour: terricolous (0), arboreal (1), limestone (2).
